

## Regression revisited

# Regression

- ▶ Use regression when one variable is an outcome (*response*,  $y$ ).
- ▶ See if/how response depends on other variable(s), *explanatory*,  $x_1, x_2, \dots$
- ▶ Can have *one or more than one* explanatory variable, but always one response.
- ▶ Assumes a *straight-line* relationship between response and explanatory.
- ▶ Ask:
  - ▶ *is there* a relationship between  $y$  and  $x$ 's, and if so, which ones?
  - ▶ what does the relationship look like?

# Packages

```
library(MASS, exclude = "select") # for Box-Cox, later
library(tidyverse)
library(broom)
library(marginaleffects)
# library(conflicted) # add these lines if you forget the c
# conflict_prefer("select", "dplyr")
```

## A regression with one $x$

13 children, measure average total sleep time (ATST, mins) and age (years) for each. See if ATST depends on age. Data in sleep.txt, ATST then age. Read in data:

```
my_url <- "http://ritsokiguess.site/datafiles/sleep.txt"
sleep <- read_delim(my_url, " ")
```

## Check data

```
summary(sleep)
```

| atst          | age            |
|---------------|----------------|
| Min. :461.8   | Min. : 4.400   |
| 1st Qu.:491.1 | 1st Qu.: 7.200 |
| Median :528.3 | Median : 8.900 |
| Mean :519.3   | Mean : 9.058   |
| 3rd Qu.:532.5 | 3rd Qu.:11.100 |
| Max. :586.0   | Max. :14.000   |

```
sleep
```

```
# A tibble: 13 x 2
```

|   | atst  | age   |
|---|-------|-------|
|   | <dbl> | <dbl> |
| 1 | 586   | 4.4   |
| 2 | 462.  | 14    |
| 3 | 491.  | 10.1  |

# The scatterplot

```
ggplot(sleep, aes(x = age, y = atst)) + geom_point()
```

# Correlation

- ▶ Measures how well a straight line fits the data:

```
with(sleep, cor(atst, age))
```

```
[1] -0.9515469
```

- ▶ 1 is perfect upward trend,  $-1$  is perfect downward trend, 0 is no trend.
- ▶ This one close to perfect downward trend.
- ▶ Can do correlations of all pairs of variables:

```
cor(sleep)
```

|      | atst       | age        |
|------|------------|------------|
| atst | 1.0000000  | -0.9515469 |
| age  | -0.9515469 | 1.0000000  |

## Lowess curve

- ▶ Sometimes nice to guide the eye: is the trend straight, or not?
- ▶ Idea: *lowess curve*. “Locally weighted least squares”, not affected by outliers, not constrained to be linear.
- ▶ Lowess is a *guide*: even if straight line appropriate, may wiggle/bend a little. Looking for *serious* problems with linearity.
- ▶ Add lowess curve to plot using `geom_smooth`:

## Plot with lowess curve

```
ggplot(sleep, aes(x = age, y = atst)) + geom_point() +  
  geom_smooth()
```

# The regression

Scatterplot shows no obvious curve, and a pretty clear downward trend. So we can run the regression:

```
sleep.1 <- lm(atst ~ age, data = sleep)
```

## The output

```
summary(sleep.1)
```

Call:

```
lm(formula = atst ~ age, data = sleep)
```

Residuals:

| Min     | 1Q     | Median | 3Q    | Max    |
|---------|--------|--------|-------|--------|
| -23.011 | -9.365 | 2.372  | 6.770 | 20.411 |

Coefficients:

|             | Estimate | Std. Error | t value | Pr(> t ) |     |
|-------------|----------|------------|---------|----------|-----|
| (Intercept) | 646.483  | 12.918     | 50.05   | 2.49e-14 | *** |
| age         | -14.041  | 1.368      | -10.26  | 5.70e-07 | *** |
| ---         |          |            |         |          |     |

Signif. codes:

0 '\*\*\*' 0.001 '\*\*' 0.01 '\*' 0.05 '.' 0.1 ' ' 1

# Conclusions

- ▶ The relationship appears to be a straight line, with a downward trend.
- ▶  $F$ -tests for model as a whole and  $t$ -test for slope (same) both confirm this (P-value  $5.7 \times 10^{-7} = 0.00000057$ ).
- ▶ Slope is  $-14$ , so a 1-year increase in age goes with a 14-minute decrease in ATST on average.
- ▶ R-squared is correlation squared (when one  $x$  anyway), between 0 and 1 (1 good, 0 bad).
- ▶ Here R-squared is 0.9054, pleasantly high.

## Doing things with the regression output

- ▶ Output from regression (and eg.  $t$ -test) is all right to look at, but hard to extract and re-use information from.
- ▶ Package broom extracts info from model output in way that can be used in pipe (later):

```
tidy(sleep.1)
```

```
# A tibble: 2 x 5
```

|   | term        | estimate | std.error | statistic | p.value  |
|---|-------------|----------|-----------|-----------|----------|
|   | <chr>       | <dbl>    | <dbl>     | <dbl>     | <dbl>    |
| 1 | (Intercept) | 646.     | 12.9      | 50.0      | 2.49e-14 |
| 2 | age         | -14.0    | 1.37      | -10.3     | 5.70e- 7 |

also one-line summary of model:

```
glance(sleep.1)
```

```
# A tibble: 1 x 12
```

|   | r.squared | adj.r.squared | sigma | statistic | p.value     | df    |
|---|-----------|---------------|-------|-----------|-------------|-------|
|   | <dbl>     | <dbl>         | <dbl> | <dbl>     | <dbl>       | <dbl> |
| 1 | 0.905     | 0.897         | 13.2  | 105.      | 0.000000570 | 1     |

```
# i 6 more variables: logLik <dbl>, AIC <dbl>, BIC <dbl>,  
#   deviance <dbl>, df.residual <int>, nobs <int>
```

## Broom part 2

```
sleep.1 %>% augment(sleep)
```

```
# A tibble: 13 x 8
```

|    | atst  | age   | .fitted | .resid | .hat   | .sigma | .cooksd |
|----|-------|-------|---------|--------|--------|--------|---------|
|    | <dbl> | <dbl> | <dbl>   | <dbl>  | <dbl>  | <dbl>  | <dbl>   |
| 1  | 586   | 4.4   | 585.    | 1.30   | 0.312  | 13.8   | 0.00320 |
| 2  | 462.  | 14    | 450.    | 11.8   | 0.341  | 13.0   | 0.319   |
| 3  | 491.  | 10.1  | 505.    | -13.6  | 0.0887 | 13.0   | 0.0568  |
| 4  | 565   | 6.7   | 552.    | 12.6   | 0.137  | 13.1   | 0.0844  |
| 5  | 462   | 11.5  | 485.    | -23.0  | 0.141  | 11.3   | 0.294   |
| 6  | 532.  | 9.6   | 512.    | 20.4   | 0.0801 | 12.0   | 0.114   |
| 7  | 478.  | 12.4  | 472.    | 5.23   | 0.198  | 13.7   | 0.0243  |
| 8  | 515.  | 8.9   | 522.    | -6.32  | 0.0772 | 13.6   | 0.0105  |
| 9  | 493   | 11.1  | 491.    | 2.37   | 0.122  | 13.8   | 0.00258 |
| 10 | 528.  | 7.75  | 538.    | -9.37  | 0.0954 | 13.4   | 0.0296  |
| 11 | 576.  | 5.5   | 569.    | 6.64   | 0.214  | 13.6   | 0.0441  |
| 12 | 532.  | 8.6   | 526.    | 6.77   | 0.0792 | 13.6   | 0.0124  |
| 13 | 530.  | 7.2   | 545.    | -14.9  | 0.114  | 12.9   | 0.0933  |

## CI for mean response and prediction intervals

Once useful regression exists, use it for prediction:

- ▶ To get a single number for prediction at a given  $x$ , substitute into regression equation, eg. age 10: predicted ATST is  $646.48 - 14.04(10) = 506$  minutes.
- ▶ To express uncertainty of this prediction:
- ▶ *CI for mean response* expresses uncertainty about mean ATST for all children aged 10, based on data.
- ▶ *Prediction interval* expresses uncertainty about predicted ATST for a new child aged 10 whose ATST not known. More uncertain.
- ▶ Also do above for a child aged 5.

# The marginalesffects package 1/2

To get predictions for specific values, set up a dataframe with those values first:

```
new <- datagrid(model = sleep.1, age = c(10, 5))  
new
```

|   | age | rowid |
|---|-----|-------|
| 1 | 10  | 1     |
| 2 | 5   | 2     |

Any variables in the dataframe that you don't specify are set to their mean values (quantitative) or most common category (categorical).

## The marginalesffects package 2/2

Then feed into newdata in predictions. This contains a lot of columns, so you probably want only to display the ones you care about:

```
cbind(predictions(sleep.1, newdata = new)) %>%  
  select(estimate, conf.low, conf.high, age)
```

|   | estimate | conf.low | conf.high | age |
|---|----------|----------|-----------|-----|
| 1 | 506.0729 | 498.4899 | 513.6558  | 10  |
| 2 | 576.2781 | 563.2588 | 589.2974  | 5   |

The confidence limits are a 95% confidence interval for the mean response at that age.

## Prediction intervals

These are obtained (instead) with `predict` as below. Use the same dataframe `new` as before:

```
pp <- predict(sleep.1, new, interval = "p")
pp
```

|   | fit      | lwr      | upr      |
|---|----------|----------|----------|
| 1 | 506.0729 | 475.8982 | 536.2475 |
| 2 | 576.2781 | 543.8474 | 608.7088 |

```
cbind(new, pp)
```

|   | age | rowid | fit      | lwr      | upr      |
|---|-----|-------|----------|----------|----------|
| 1 | 10  | 1     | 506.0729 | 475.8982 | 536.2475 |
| 2 | 5   | 2     | 576.2781 | 543.8474 | 608.7088 |

## Plotting the confidence intervals for mean response again:

```
plot_predictions(sleep.1, condition = "age")
```

## Comments

- ▶ Age 10 closer to centre of data, so intervals are both narrower than those for age 5.
- ▶ Prediction intervals bigger than CI for mean (additional uncertainty).
- ▶ Technical note: output from `predict` is R matrix, not data frame, so Tidyverse `bind_cols` does not work. Use base R `cbind`.

## That grey envelope

Marks confidence interval for mean for all  $x$ :

```
ggplot(sleep, aes(x = age, y = atst)) + geom_point() +  
  geom_smooth(method = "lm") +  
  scale_y_continuous(breaks = seq(420, 600, 20))
```

# Diagnostics

How to tell whether a straight-line regression is appropriate?

- ▶ Before: check scatterplot for straight trend.
- ▶ After: plot *residuals* (observed minus predicted response) against predicted values. Aim: a plot with no pattern.

# Residual plot

Not much pattern here — regression appropriate.

```
ggplot(sleep.1, aes(x = .fitted, y = .resid)) + geom_point
```

## An inappropriate regression

Different data:

```
my_url <- "http://ritsokiguess.site/datafiles/curvy.txt"  
curvy <- read_delim(my_url, " ")
```

# Scatterplot

```
ggplot(curvy, aes(x = xx, y = yy)) + geom_point()
```

# Regression line, anyway

```
curvy.1 <- lm(yy ~ xx, data = curvy)
summary(curvy.1)
```

Call:

```
lm(formula = yy ~ xx, data = curvy)
```

Residuals:

| Min    | 1Q     | Median | 3Q    | Max   |
|--------|--------|--------|-------|-------|
| -3.582 | -2.204 | 0.000  | 1.514 | 3.509 |

Coefficients:

|             | Estimate | Std. Error | t value | Pr(> t ) |    |
|-------------|----------|------------|---------|----------|----|
| (Intercept) | 7.5818   | 1.5616     | 4.855   | 0.00126  | ** |
| xx          | 0.9818   | 0.2925     | 3.356   | 0.00998  | ** |

---

Signif. codes:

0 '\*\*\*' 0.001 '\*\*' 0.01 '\*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 2.657 on 8 degrees of freedom

Multiple R-squared: 0.5848, Adjusted R-squared: 0.5329

F-statistic: 11.27 on 1 and 8 DF, p-value: 0.009984

# Residual plot

```
ggplot(curvy.1, aes(x = .fitted, y = .resid)) + geom_point()
```

## No good: fixing it up

- ▶ Residual plot has *curve*: middle residuals positive, high and low ones negative. Bad.
- ▶ Fitting a curve would be better. Try this:

```
curvy.2 <- lm(yy ~ xx + I(xx^2), data = curvy)
```

- ▶ Adding xx-squared term, to allow for curve.
- ▶ Another way to do same thing: specify how model *changes*:

```
curvy.2a <- update(curvy.1, . ~ . + I(xx^2))
```

## Regression 2

```
tidy(curvy.2)
```

```
# A tibble: 3 x 5
```

|   | term<br><chr> | estimate<br><dbl> | std.error<br><dbl> | statistic<br><dbl> | p.value<br><dbl> |
|---|---------------|-------------------|--------------------|--------------------|------------------|
| 1 | (Intercept)   | 3.9               | 0.773              | 5.04               | 0.00149          |
| 2 | xx            | 3.74              | 0.400              | 9.36               | 0.0000331        |
| 3 | I(xx^2)       | -0.307            | 0.0428             | -7.17              | 0.000182         |

```
glance(curvy.2) #
```

```
# A tibble: 1 x 12
```

|   | r.squared<br><dbl> | adj.r.squared<br><dbl> | sigma<br><dbl> | statistic<br><dbl> | p.value<br><dbl> | df<br><dbl> |
|---|--------------------|------------------------|----------------|--------------------|------------------|-------------|
| 1 | 0.950              | 0.936                  | 0.983          | 66.8               | 0.0000275        | 2           |

```
# i 6 more variables: logLik <dbl>, AIC <dbl>, BIC <dbl>,  
# deviance <dbl>, df.residual <int>, nobs <int>
```

## Comments

- ▶  $xx$ -squared term definitely significant (P-value 0.000182), so need this curve to describe relationship.
- ▶ Adding squared term has made R-squared go up from 0.5848 to 0.9502: great improvement.
- ▶ This is a definite curve!

# The residual plot now

No problems any more:

```
ggplot(curvy.2, aes(x = .fitted, y = .resid)) + geom_point()
```

## Another way to handle curves

- ▶ Above, saw that changing  $x$  (adding  $x^2$ ) was a way of handling curved relationships.
- ▶ Another way: change  $y$  (transformation).
- ▶ Can guess how to change  $y$ , or might be theory:
- ▶ example: relationship  $y = ae^{bx}$  (exponential growth):
- ▶ take logs to get  $\ln y = \ln a + bx$ .
- ▶ Taking logs has made relationship linear ( $\ln y$  as response).
- ▶ Or, *estimate* transformation, using Box-Cox method.

## Box-Cox

- ▶ Install package MASS via `install.packages("MASS")` (only need to do *once*)
- ▶ Every R session you want to use something in MASS, type `library(MASS)`

## Some made-up data

```
my_url <- "http://ritsokiguess.site/datafiles/madeup2.csv"
madeup <- read_csv(my_url)
madeup
```

```
# A tibble: 8 x 3
  ...1      x      y
  <dbl> <dbl> <dbl>
1      1      0  17.9
2      2      1  33.6
3      3      2  82.7
4      4      3  31.2
5      5      4 177.
6      6      5 359.
7      7      6 469.
8      8      7 283.
```

Seems to be faster-than-linear growth, maybe exponential growth.

# Scatterplot: faster than linear growth

```
ggplot(madeup, aes(x = x, y = y)) + geom_point() +  
  geom_smooth()
```

# Running Box-Cox

- ▶ `library(MASS)` first.
- ▶ Feed `boxcox` a model formula with a squiggle in it, such as you would use for `lm`.
- ▶ Output: a graph (next page):

```
boxcox(y ~ x, data = madeup)
```

# The Box-Cox output

## Comments

- ▶  $\lambda$  (lambda) is the power by which you should transform  $y$  to get the relationship straight (straighter). Power 0 is “take logs”
- ▶ Middle dotted line marks best single value of  $\lambda$  (here about 0.1).
- ▶ Outer dotted lines mark 95% CI for  $\lambda$ , here  $-0.3$  to  $0.7$ , approx. (Rather uncertain about best transformation.)
- ▶ Any power transformation within the CI supported by data. In this case, log ( $\lambda = 0$ ) and square root ( $\lambda = 0.5$ ) good, but no transformation ( $\lambda = 1$ ) not.
- ▶ Pick a “round-number” value of  $\lambda$  like 2, 1, 0.5, 0,  $-0.5$ ,  $-1$ . Here 0 and 0.5 good values to pick.

# Did transformation straighten things?

- Plot transformed  $y$  against  $x$ . Here, log:

```
ggplot(madeup, aes(x = x, y = log(y))) + geom_point() +  
  geom_smooth()
```

Looks much straighter.

## Regression with transformed $y$

```
madeup.1 <- lm(log(y) ~ x, data = madeup)
glance(madeup.1)
```

```
# A tibble: 1 x 12
```

|   | r.squared | adj.r.squared | sigma | statistic | p.value | df    |
|---|-----------|---------------|-------|-----------|---------|-------|
|   | <dbl>     | <dbl>         | <dbl> | <dbl>     | <dbl>   | <dbl> |
| 1 | 0.811     | 0.779         | 0.588 | 25.7      | 0.00228 | 1     |

```
# i 6 more variables: logLik <dbl>, AIC <dbl>, BIC <dbl>,
#   deviance <dbl>, df.residual <int>, nobs <int>
```

```
tidy(madeup.1)
```

```
# A tibble: 2 x 5
```

|   | term        | estimate | std.error | statistic | p.value  |
|---|-------------|----------|-----------|-----------|----------|
|   | <chr>       | <dbl>    | <dbl>     | <dbl>     | <dbl>    |
| 1 | (Intercept) | 3.03     | 0.379     | 7.98      | 0.000206 |
| 2 | x           | 0.460    | 0.0907    | 5.07      | 0.00228  |

```
R squared now decently high
```

# Multiple regression

- ▶ What if more than one  $x$ ? Extra issues:
  - ▶ Now one intercept and a slope for each  $x$ : how to interpret?
  - ▶ Which  $x$ -variables actually help to predict  $y$ ?
  - ▶ Different interpretations of “global”  $F$ -test and individual  $t$ -tests.
  - ▶ R-squared no longer correlation squared, but still interpreted as “higher better”.
  - ▶ In `lm` line, add extra  $x$ s after `~`.
  - ▶ Interpretation not so easy (and other problems that can occur).

## Multiple regression example

Study of women and visits to health professionals, and how the number of visits might be related to other variables:

`timedrs`: number of visits to health professionals (over course of study)

`phyheal`: number of physical health problems

`menheal`: number of mental health problems

`stress`: result of questionnaire about number and type of life changes

`timedrs` response, others explanatory.

## The data

```
my_url <-  
  "http://ritsokiguess.site/datafiles/regressx.txt"  
visits <- read_delim(my_url, " ")
```

## Check data

```
visits
```

```
# A tibble: 465 x 5
```

|    | subjno | timedrs | phyheal | menheal | stress |
|----|--------|---------|---------|---------|--------|
|    | <dbl>  | <dbl>   | <dbl>   | <dbl>   | <dbl>  |
| 1  | 1      | 1       | 5       | 8       | 265    |
| 2  | 2      | 3       | 4       | 6       | 415    |
| 3  | 3      | 0       | 3       | 4       | 92     |
| 4  | 4      | 13      | 2       | 2       | 241    |
| 5  | 5      | 15      | 3       | 6       | 86     |
| 6  | 6      | 3       | 5       | 5       | 247    |
| 7  | 7      | 2       | 5       | 6       | 13     |
| 8  | 8      | 0       | 4       | 5       | 12     |
| 9  | 9      | 7       | 5       | 4       | 269    |

# i 455 more rows
```

## Fit multiple regression

```
visits.1 <- lm(timedrs ~ phyheal + menheal + stress,  
  data = visits)  
summary(visits.1)
```

Call:

```
lm(formula = timedrs ~ phyheal + menheal + stress, data = v
```

Residuals:

| Min     | 1Q     | Median | 3Q    | Max    |
|---------|--------|--------|-------|--------|
| -14.792 | -4.353 | -1.815 | 0.902 | 65.886 |

Coefficients:

|             | Estimate  | Std. Error | t value | Pr(> t ) |     |
|-------------|-----------|------------|---------|----------|-----|
| (Intercept) | -3.704848 | 1.124195   | -3.296  | 0.001058 | **  |
| phyheal     | 1.786948  | 0.221074   | 8.083   | 5.6e-15  | *** |
| menheal     | -0.009666 | 0.129029   | -0.075  | 0.940318 |     |
| stress      | 0.013615  | 0.003612   | 3.769   | 0.000185 | *** |

## The slopes

- ▶ Model as a whole strongly significant even though R-sq not very big (lots of data). At least one of the  $x$ 's predicts `timedrs`.
- ▶ The physical health and stress variables definitely help to predict the number of visits, but *with those in the model* we don't need `menheal`. However, look at prediction of `timedrs` from `menheal` by itself:

## Just menheal

```
visits.2 <- lm(timedrs ~ menheal, data = visits)
summary(visits.2)
```

Call:

```
lm(formula = timedrs ~ menheal, data = visits)
```

Residuals:

| Min     | 1Q     | Median | 3Q    | Max    |
|---------|--------|--------|-------|--------|
| -13.826 | -5.150 | -2.818 | 1.177 | 72.513 |

Coefficients:

|             | Estimate | Std. Error | t value | Pr(> t ) |     |
|-------------|----------|------------|---------|----------|-----|
| (Intercept) | 3.8159   | 0.8702     | 4.385   | 1.44e-05 | *** |
| menheal     | 0.6672   | 0.1173     | 5.688   | 2.28e-08 | *** |
| ---         |          |            |         |          |     |

Signif. codes:

0 '\*\*\*' 0.001 '\*\*' 0.01 '\*' 0.05 '.' 0.1 ' ' 1

## menheal by itself

- ▶ menheal by itself *does* significantly help to predict timedrs.
- ▶ But the R-sq is much less (6.5% vs. 22%).
- ▶ So other two variables do a better job of prediction.
- ▶ With those variables in the regression (phyheal and stress), don't need menheal *as well*.

## Investigating via correlation

Leave out first column (subjno):

```
visits %>% select(-subjno) %>% cor()
```

|         | timedrs   | phyheal   | menheal   | stress    |
|---------|-----------|-----------|-----------|-----------|
| timedrs | 1.0000000 | 0.4395293 | 0.2555703 | 0.2865951 |
| phyheal | 0.4395293 | 1.0000000 | 0.5049464 | 0.3055517 |
| menheal | 0.2555703 | 0.5049464 | 1.0000000 | 0.3697911 |
| stress  | 0.2865951 | 0.3055517 | 0.3697911 | 1.0000000 |

- ▶ phyheal most strongly correlated with timedrs.
- ▶ Not much to choose between other two.
- ▶ But menheal has higher correlation with phyheal, so not as much to *add* to prediction as stress.
- ▶ Goes to show things more complicated in multiple regression.

## Residual plot (from timedrs on all)

```
ggplot(visits.1, aes(x = .fitted, y = .resid)) + geom_point
```

Apparently random. But...

# Normal quantile plot of residuals

```
ggplot(visits.1, aes(sample = .resid)) + stat_qq() + stat_c
```

Not normal at all; upper tail is way too long.

# Absolute residuals

Is there trend in *size* of residuals (fan-out)? Plot *absolute value* of residual against fitted value:

```
ggplot(visits.1, aes(x = .fitted, y = abs(.resid))) +  
  geom_point() + geom_smooth()
```

## Comments

- ▶ On the normal quantile plot:
  - ▶ highest (most positive) residuals are way too high
  - ▶ distribution of residuals skewed to right (not normal at all)
- ▶ On plot of absolute residuals:
  - ▶ size of residuals getting bigger as fitted values increase
  - ▶ predictions getting more variable as fitted values increase
  - ▶ that is, predictions getting *less accurate* as fitted values increase, but predictions should be equally accurate all way along.
- ▶ Both indicate problems with regression, of kind that transformation of response often fixes: that is, predict *function* of response `timedrs` instead of `timedrs` itself.

## Box-Cox transformations

- ▶ Taking log of `timedrs` and having it work: lucky guess. How to find good transformation?
- ▶ Box-Cox again.
- ▶ Extra problem: some of `timedrs` values are 0, but Box-Cox expects all  $+$ . Note response for `boxcox`:

```
boxcox(timedrs + 1 ~ phyheal + menheal + stress, data = vis
```

# Try 1

## Comments on try 1

- ▶ Best:  $\lambda$  just less than zero.
- ▶ Hard to see scale.
- ▶ Focus on  $\lambda$  in  $(-0.3, 0.1)$ :

```
my.lambda <- seq(-0.3, 0.1, 0.01)  
my.lambda
```

```
[1] -0.30 -0.29 -0.28 -0.27 -0.26 -0.25 -0.24 -0.23 -0.22  
[10] -0.21 -0.20 -0.19 -0.18 -0.17 -0.16 -0.15 -0.14 -0.13  
[19] -0.12 -0.11 -0.10 -0.09 -0.08 -0.07 -0.06 -0.05 -0.04  
[28] -0.03 -0.02 -0.01  0.00  0.01  0.02  0.03  0.04  0.05  
[37]  0.06  0.07  0.08  0.09  0.10
```

## Try 2

```
boxcox(timedrs + 1 ~ phyheal + menheal + stress,  
       lambda = my.lambda,  
       data = visits  
)
```

## Comments

- ▶ Best:  $\lambda$  just about  $-0.07$ .
- ▶ CI for  $\lambda$  about  $(-0.14, 0.01)$ .
- ▶ Only nearby round number:  $\lambda = 0$ , log transformation.

## Fixing the problems

- ▶ Try regression again, with transformed response instead of original one.
- ▶ Then check residual plot to see that it is OK now.

```
visits.3 <- lm(log(timedrs + 1) ~ phyheal + menheal + stres  
  data = visits  
)
```

- ▶ timedrs+1 because some timedrs values 0, can't take log of 0.
- ▶ Won't usually need to worry about this, but when response could be zero/negative, fix that before transformation.

# Output

```
summary(visits.3)
```

Call:

```
lm(formula = log(timedrs + 1) ~ phyheal + menheal + stress, data = visits)
```

Residuals:

|  | Min      | 1Q       | Median   | 3Q      | Max     |
|--|----------|----------|----------|---------|---------|
|  | -1.95865 | -0.44076 | -0.02331 | 0.42304 | 2.36797 |

Coefficients:

|             | Estimate  | Std. Error | t value | Pr(> t ) |     |
|-------------|-----------|------------|---------|----------|-----|
| (Intercept) | 0.3903862 | 0.0882908  | 4.422   | 1.22e-05 | *** |
| phyheal     | 0.2019361 | 0.0173624  | 11.631  | < 2e-16  | *** |
| menheal     | 0.0071442 | 0.0101335  | 0.705   | 0.481    |     |
| stress      | 0.0013158 | 0.0002837  | 4.638   | 4.58e-06 | *** |

---

Signif. codes:

0 '\*\*\*' 0.001 '\*\*' 0.01 '\*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 0.7625 on 461 degrees of freedom

Multiple R-squared: 0.3682, Adjusted R-squared: 0.3641

F-statistic: 89.56 on 3 and 461 DF, p-value: < 2.2e-16

## Comments

- ▶ Model as a whole strongly significant again
- ▶ R-sq higher than before (37% vs. 22%) suggesting things more linear now
- ▶ Same conclusion re `menheal`: can take out of regression.
- ▶ Should look at residual plots (next pages). Have we fixed problems?

# Residuals against fitted values

```
ggplot(visits.3, aes(x = .fitted, y = .resid)) +  
  geom_point()
```

## Normal quantile plot of residuals

```
ggplot(visits.3, aes(sample = .resid)) + stat_qq() + stat_c
```

# Absolute residuals against fitted

```
ggplot(visits.3, aes(x = .fitted, y = abs(.resid))) +  
  geom_point() + geom_smooth()
```

## Comments

- ▶ Residuals vs. fitted looks a lot more random.
- ▶ Normal quantile plot looks a lot more normal (though still a little right-skewness)
- ▶ Absolute residuals: not so much trend (though still some).
- ▶ Not perfect, but much improved.

## Testing more than one $x$ at once

- ▶ The  $t$ -tests test only whether one variable could be taken out of the regression you're looking at.
- ▶ To test significance of more than one variable at once, fit model with and without variables
  - ▶ then use `anova` to compare fit of models:

```
visits.5 <- lm(log(timedrs + 1) ~ phyheal + menheal + stress, data = visits)
visits.6 <- lm(log(timedrs + 1) ~ stress, data = visits)
```

## Results of tests

```
anova(visits.6, visits.5)
```

### Analysis of Variance Table

Model 1:  $\log(\text{timedrs} + 1) \sim \text{stress}$

Model 2:  $\log(\text{timedrs} + 1) \sim \text{phyheal} + \text{menheal} + \text{stress}$

|   | Res.Df | RSS    | Df | Sum of Sq | F      | Pr(>F)        |
|---|--------|--------|----|-----------|--------|---------------|
| 1 | 463    | 371.47 |    |           |        |               |
| 2 | 461    | 268.01 | 2  | 103.46    | 88.984 | < 2.2e-16 *** |

---

Signif. codes:

0 '\*\*\*' 0.001 '\*\*' 0.01 '\*' 0.05 '.' 0.1 ' ' 1

- ▶ Models don't fit equally well, so bigger one fits better.
- ▶ Or “taking both variables out makes the fit worse, so don't do it”.
- ▶ Taking out those  $x$ 's is a mistake. Or putting them in is a good idea.

## The punting data

Data set `punting.txt` contains 4 variables for 13 right-footed football kickers (punters): left leg and right leg strength (lbs), distance punted (ft), another variable called “fred”. Predict punting distance from other variables:

| left | right | punt   | fred |
|------|-------|--------|------|
| 170  | 170   | 162.50 | 171  |
| 130  | 140   | 144.0  | 136  |
| 170  | 180   | 174.50 | 174  |
| 160  | 160   | 163.50 | 161  |
| 150  | 170   | 192.0  | 159  |
| 150  | 150   | 171.75 | 151  |
| 180  | 170   | 162.0  | 174  |
| 110  | 110   | 104.83 | 111  |
| 110  | 120   | 105.67 | 114  |
| 120  | 130   | 117.58 | 126  |
| 140  | 120   | 140.25 | 129  |
| 130  | 140   | 150.17 | 136  |
| 150  | 160   | 165.17 | 154  |

## Reading in

- ▶ Separated by *multiple spaces* with *columns lined up*:

```
my_url <- "http://ritsokiguess.site/datafiles/punting.txt"  
punting <- read_table(my_url)
```

# The data

punting

```
# A tibble: 13 x 4
  left right  punt  fred
<dbl> <dbl> <dbl> <dbl>
1   170   170  162.   171
2   130   140  144    136
3   170   180  174.   174
4   160   160  164.   161
5   150   170  192    159
6   150   150  172.   151
7   180   170  162    174
8   110   110  105.   111
9   110   120  106.   114
10  120   130  118.   126
11  140   120  140.   129
12  130   140  150.   136
13  150   160  165.   154
```

## Regression and output

```
punting.1 <- lm(punt ~ left + right + fred, data = punting)  
glance(punting.1)
```

```
# A tibble: 1 x 12
```

|   | r.squared | adj.r.squared | sigma | statistic | p.value | df    |
|---|-----------|---------------|-------|-----------|---------|-------|
|   | <dbl>     | <dbl>         | <dbl> | <dbl>     | <dbl>   | <dbl> |
| 1 | 0.778     | 0.704         | 14.7  | 10.5      | 0.00267 | 3     |

```
# i 6 more variables: logLik <dbl>, AIC <dbl>, BIC <dbl>,  
# deviance <dbl>, df.residual <int>, nobs <int>
```

```
tidy(punting.1)
```

```
# A tibble: 4 x 5
```

|   | term        | estimate | std.error | statistic | p.value |
|---|-------------|----------|-----------|-----------|---------|
|   | <chr>       | <dbl>    | <dbl>     | <dbl>     | <dbl>   |
| 1 | (Intercept) | -4.69    | 29.1      | -0.161    | 0.876   |
| 2 | left        | 0.268    | 2.11      | 0.127     | 0.902   |
| 3 | right       | 1.05     | 2.15      | 0.490     | 0.636   |

## Comments

- ▶ Overall regression strongly significant, R-sq high.
- ▶ None of the  $x$ 's significant! Why?
- ▶  $t$ -tests only say that you could take any one of the  $x$ 's out without damaging the fit; doesn't matter which one.
- ▶ Explanation: look at *correlations*.

## The correlations

```
cor(punting)
```

|       | left      | right     | punt      | fred      |
|-------|-----------|-----------|-----------|-----------|
| left  | 1.0000000 | 0.8957224 | 0.8117368 | 0.9722632 |
| right | 0.8957224 | 1.0000000 | 0.8805469 | 0.9728784 |
| punt  | 0.8117368 | 0.8805469 | 1.0000000 | 0.8679507 |
| fred  | 0.9722632 | 0.9728784 | 0.8679507 | 1.0000000 |

- ▶ All correlations are high:  $x$ 's with punt (good) and with each other (bad, at least confusing).
- ▶ What to do? Probably do just as well to pick one variable, say right since kickers are right-footed.

## Just right

```
punting.2 <- lm(punt ~ right, data = punting)
summary(punting.2)
```

Call:

```
lm(formula = punt ~ right, data = punting)
```

Residuals:

|  | Min      | 1Q       | Median | 3Q     | Max     |
|--|----------|----------|--------|--------|---------|
|  | -15.7576 | -11.0611 | 0.3656 | 7.8890 | 19.0423 |

Coefficients:

|             | Estimate | Std. Error | t value | Pr(> t )     |
|-------------|----------|------------|---------|--------------|
| (Intercept) | -3.6930  | 25.2649    | -0.146  | 0.886        |
| right       | 1.0427   | 0.1692     | 6.162   | 7.09e-05 *** |
| ---         |          |            |         |              |

Signif. codes:

0 '\*\*\*' 0.001 '\*\*' 0.01 '\*' 0.05 '.' 0.1 ' ' 1

## Comparing R-squareds

```
summary(punting.1)$r.squared
```

```
[1] 0.7781401
```

```
summary(punting.2)$r.squared
```

```
[1] 0.7753629
```

Basically no difference. In regression (over), right significant:

## Regression results

```
tidy(punting.2)
```

```
# A tibble: 2 x 5
```

|   | term        | estimate | std.error | statistic | p.value   |
|---|-------------|----------|-----------|-----------|-----------|
|   | <chr>       | <dbl>    | <dbl>     | <dbl>     | <dbl>     |
| 1 | (Intercept) | -3.69    | 25.3      | -0.146    | 0.886     |
| 2 | right       | 1.04     | 0.169     | 6.16      | 0.0000709 |

But...

- ▶ Maybe we got the *form* of the relationship with `left` wrong.
- ▶ Check: plot *residuals* from previous regression (without `left`) against `left`.
- ▶ Residuals here are “punting distance adjusted for right leg strength”.
- ▶ If there is some kind of relationship with `left`, we should include in model.
- ▶ Plot of residuals against original variable: `augment` from `broom`.

## Augmenting punting.2

```
punting.2 %>% augment(punting) -> punting.2.aug  
punting.2.aug
```

```
# A tibble: 13 x 10
```

|    | left<br><dbl> | right<br><dbl> | punt<br><dbl> | fred<br><dbl> | .fitted<br><dbl> | .resid<br><dbl> | .hat<br><dbl> | .sigma<br><dbl> |

# Residuals against left

```
ggplot(punting.2.aug, aes(x = left, y = .resid)) +  
  geom_point()
```

## Comments

- ▶ There is a *curved* relationship with left.
- ▶ We should add left-squared to the regression (and therefore put left back in when we do that):

```
punting.3 <- lm(punt ~ left + I(left^2) + right,  
  data = punting  
)
```

# Regression with left-squared

```
summary(punting.3)
```

Call:

```
lm(formula = punt ~ left + I(left^2) + right, data = punting)
```

Residuals:

|  | Min      | 1Q      | Median | 3Q     | Max     |
|--|----------|---------|--------|--------|---------|
|  | -11.3777 | -5.3599 | 0.0459 | 4.5088 | 13.2669 |

Coefficients:

|             | Estimate   | Std. Error | t value | Pr(> t ) |    |
|-------------|------------|------------|---------|----------|----|
| (Intercept) | -4.623e+02 | 9.902e+01  | -4.669  | 0.00117  | ** |
| left        | 6.888e+00  | 1.462e+00  | 4.710   | 0.00110  | ** |
| I(left^2)   | -2.302e-02 | 4.927e-03  | -4.672  | 0.00117  | ** |
| right       | 7.396e-01  | 2.292e-01  | 3.227   | 0.01038  | *  |
| ---         |            |            |         |          |    |

Signif. codes:

0 '\*\*\*' 0.001 '\*\*' 0.01 '\*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 7.931 on 9 degrees of freedom

Multiple R-squared: 0.9352, Adjusted R-squared: 0.9136

F-statistic: 43.3 on 3 and 9 DF, p-value: 1.13e-05

## Comments

- ▶ This was definitely a good idea (R-squared has clearly increased).
- ▶ We would never have seen it without plotting residuals from `punting.2 (without left)` against `left`.
- ▶ Negative slope for `leftsq` means that increased left-leg strength only increases punting distance up to a point: beyond that, it decreases again.
