Tidying data

Tidying data

- Data rarely come to us as we want to use them.
- ▶ Before we can do analysis, typically have organizing to do.
- ► This is typical of ANOVA-type data, "wide format":

```
      pig feed1 feed2 feed3 feed4

      1 60.8 68.7 92.6 87.9

      2 57.0 67.7 92.1 84.2

      3 65.0 74.0 90.2 83.1

      4 58.6 66.3 96.5 85.7

      5 61.7 69.8 99.1 90.3
```

- ▶ 20 pigs randomly allocated to one of four feeds. At end of study, weight of each pig is recorded.
- Are any differences in mean weights among the feeds?
- Problem: want all weights in one column, with 2nd column labelling which feed. Untidy!

Tidy and untidy data (Wickham)

- Data set easier to deal with if:
 - each observation is one row
 - each variable is one column
 - each type of observation unit is one table
- Data arranged this way called "tidy"; otherwise called "untidy".
- For the pig data:
 - response variable is weight, but scattered over 4 columns, which are levels of a factor feed.
 - Want all the weights in one column, with a second column feed saying which feed that weight goes with.
 - Then we can run aov.

Packages for this section

library(tidyverse)

Reading in the pig data

```
my url <- "http://ritsokiguess.site/datafiles/pigs1.txt"
pigs1 <- read_delim(my_url, " ")</pre>
pigs1
# A tibble: 5 x 5
   pig feed1 feed2 feed3 feed4
  <dbl> <dbl> <dbl> <dbl> <dbl> <dbl>
     1 60.8 68.7 92.6 87.9
2
     2 57 67.7 92.1 84.2
     3 65 74 90.2 83.1
3
   4 58.6 66.3 96.5 85.7
4
5
     5 61.7 69.8 99.1 90.3
```

Making it longer

- ➤ We wanted all the weights in one column, labelled by which feed they went with.
- ▶ This is a very common reorganization, and the magic "verb" is pivot_longer:

Alternatives

Any way of choosing the columns to pivot longer is good, eg:

```
# A tibble: 20 x 3
    pig feed weight
   <dbl> <dbl> <dbl>
      1 feed1 60.8
      1 feed2 68.7
3
      1 feed3 92.6
4
      1 feed4
                87.9
 5
      2 feed1 57
 6
      2 feed2 67.7
      2 feed3 92.1
8
      2 feed4 84.2
9
      3 feed1
                65
10
      3 feed2
                74
```

Comments

- pigs2 now in "long" format, ready for analysis.
- Anatomy of pivot_longer:
 - columns to combine
 - a name for column that will contain groups ("names")
 - ▶ a name for column that will contain measurements ("values")

Identifying the pigs

- ➤ Values in pig identify pigs within each group: pig 1 is four different pigs!
- Create unique pig IDs by gluing pig number onto feed:

```
pigs2 %>% mutate(pig_id=str_c(feed, "_", pig)) -> pigs2
pigs2
```

```
# A tibble: 20 x 4
    pig feed weight pig_id
  <dbl> <chr> <dbl> <chr>
      1 feed1 60.8 feed1 1
2
      1 feed2 68.7 feed2 1
3
      1 feed3 92.6 feed3 1
4
    1 feed4 87.9 feed4 1
5
    2 feed1 57 feed1 2
6
      2 feed2 67.7 feed2 2
7
      2 feed3 92.1 feed3 2
      2 feed4
               84.2 feed4 2
```

...and finally, the analysis

which is just what we saw before:

```
weight.1 <- aov(weight ~ feed, data = pigs2)
summary(weight.1)</pre>
```

```
feed 3 3521 1173.5 119.1 3.72e-11 ***
Residuals 16 158 9.8
---
Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 '
```

Df Sum Sq Mean Sq F value Pr(>F)

- The mean weights of pigs on the different feeds are definitely not all equal.
- So we run Tukey to see which ones differ (over).

Tukey

TukeyHSD(weight.1)

```
Tukey multiple comparisons of means 95% family-wise confidence level
```

```
Fit: aov(formula = weight ~ feed, data = pigs2)
```

\$feed

```
diff lwr upr p adj
feed2-feed1 8.68 3.001038 14.358962 0.0024000
feed3-feed1 33.48 27.801038 39.158962 0.0000000
feed4-feed1 25.62 19.941038 31.298962 0.0000000
feed3-feed2 24.80 19.121038 30.478962 0.0000000
feed4-feed2 16.94 11.261038 22.618962 0.0000013
feed4-feed3 -7.86 -13.538962 -2.181038 0.0055599
```

All of the feeds differ!

Mean weights by feed

To find the best and worst, get mean weight by feed group. I borrowed an idea from earlier to put the means in descending order:

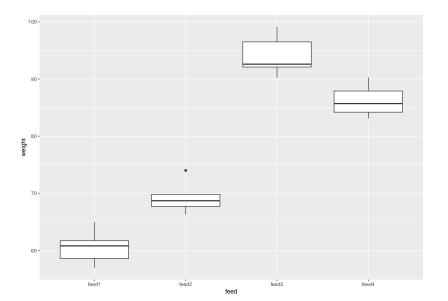

```
pigs2 %>%
  group_by(feed) %>%
  summarize(mean_weight = mean(weight))%>%
  arrange(desc(mean_weight))
```

```
# A tibble: 4 x 2
feed mean_weight
<chr> <dbl>
1 feed3 94.1
2 feed4 86.2
3 feed2 69.3
4 feed1 60.6
```

Feed 3 is best, feed 1 worst.

Should we have any concerns about the ANOVA?

ggplot(pigs2, aes(x = feed, y = weight)) + geom_boxplot()

Comments

- Feed 2 has an outlier
- But there are only 5 pigs in each group
- ▶ The conclusion is so clear that I am OK with this.

Tuberculosis

- ▶ The World Health Organization keeps track of number of cases of various diseases, eg. tuberculosis.
- Some data:

```
my_url <- "http://ritsokiguess.site/datafiles/tb.csv"
tb <- read_csv(my_url)</pre>
```

The data (randomly chosen rows)

tb %>% slice_sample(n = 10)

f65 <dbl>, fu <dbl>

A tibble: 10 x 22

10 MA 2006 4 69 73 2104 2373 1498 1036 # i 11 more variables: mu <dbl>, f04 <dbl>, f514 <dbl>, f09

f1524 <dbl>, f2534 <dbl>, f3544 <dbl>, f4554 <dbl>, f5

What we have

- Variables: country (abbreviated), year. Then number of cases for each gender and age group, eg. m1524 is males aged 15–24. Also mu and fu, where age is unknown.
- Lots of missings. Want to get rid of.
- Abbreviations here.

- Code for pivot_longer:
 - columns to make longer
 - column to contain the names (categorical)
 - column to contain the values (quantitative)
 - drop missings in the values

Results (some)

tb2

```
# A tibble: 35,750 x 4
  iso2 year genage freq
  <chr> <dbl> <chr> <dbl>
1 AD 1996 m014
2 AD 1996 m1524
3 AD 1996 m2534
4 AD 1996 m3544
5 AD 1996 m4554
6 AD 1996 m5564
7 AD
        1996 m65
8 AD

9 AD 1996 f1524
10 AD
      1996 f2534
# i 35,740 more rows
```

Separating

- 4 columns, but 5 variables, since genage contains both gender and age group. Split that up using separate.
- separate needs 3 things:
 - what to separate (no quotes needed), what to separate into (here you do need quotes),
- how to split. For "how to split", here "after first character":

1 AD 1996 m 014 2 AD 1996 m 1524 3 AD 1996 m 2534

```
tb2 %>% separate_wider_position(genage,
                                 widths = c("gender" = 1, "a
```

```
# A tibble: 35,750 x 5
  iso2 year gender age freq
```

<chr> <dbl> <chr> <dbl> <chr> <dbl>

too few = "align start") -: tb3

Tidied tuberculosis data (some)

tb3

```
# A tibble: 35,750 x 5
  iso2 year gender age freq
  <chr> <dbl> <chr> <chr> <dbl>
1 AD
        1996 m

2 AD 1996 m 1524
3 AD 1996 m
              2534
4 AD 1996 m
              3544
5 AD 1996 m
              4554
6 AD 1996 m
                5564
7 AD
        1996 m
                  65
8 AD
        1996 f
                  014
9 AD
        1996 f
                   1524
10 AD
        1996 f
                  2534
# i 35,740 more rows
```

In practice...

instead of doing the pipe one step at a time, you *debug* it one step at a time, and when you have each step working, you use that step's output as input to the next step, thus:

widths = c("gender" = 1, "age" =

too_few = "align_start")

A tibble: 35,750 x 5
 iso2 year gender age freq
 <chr> <dbl> <chr> <dbl> chr> <dbl> 014 0
2 AD 1996 m 1524 0
3 AD 1996 m 2534 0

3544

1996 m

4 AD

Total tuberculosis cases by year (some of the years)

```
tb3 %>%
  filter(between(year, 1991, 1998)) %>%
  group_by(year) %>% summarize(total=sum(freq))
```

```
# A tibble: 8 x 2
  vear total
 <dbl> <dbl>
1 1991 544
2 1992 512
3 1993 492
4 1994 750
5 1995 513971
6 1996 635705
7 1997 733204
  1998 840389
```

Something very interesting happened between 1994 and 1995.

To find out what

try counting up total cases by country:

```
tb3 %>% group_by(iso2) %>%
  summarize(total=sum(freq)) %>%
  arrange(desc(total))
```

```
# A tibble: 213 \times 2
   iso2
           total
   <chr> <dbl>

```

What years do I have for China?

China started recording in 1995, which is at least part of the problem:

```
tb3 %>% filter(iso2=="CN") %>%
  group_by(year) %>%
  summarize(total=sum(freq))
```

```
# A tibble: 14 x 2
    year total
    <dbl>    <dbl>
1 1995 131194
2 1996 168270
3 1997 195895
```

1998 214404

1999 212258 2000 213766

2001 212766 2002 194972

5

6 7

First year of recording by country?

▶ A lot of countries started recording in about 1995, in fact:

```
tb3 %>% group_by(iso2) %>%
  summarize(first_year=min(year)) %>%
  count(first_year)
```

```
# A tibble: 14 \times 2
   first year
        <dbl> <int>
         1980
         1994
 3
         1995 130
         1996 31
 5
         1997 17
 6
         1998
                6
         1999
                 10
 8
         2000
         2001
```

tmin

The columns

- ▶ Daily weather records for "Toronto City" weather station in 2018:
 - > station: identifier for this weather station (always same here)
 - Year, Month
 - element: whether temperature given was daily max or daily min
 - ▶ d01, d02,... d31: day of the month from 1st to 31st.

Off we go

Numbers in data frame all temperatures (for different days of the month), so first step is

# 1	A tibble:	703	x 6				
	${\tt station}$		Year	${\tt Month}$	${\tt element}$	day	temperature
	<chr></chr>		<dbl></dbl>	<chr></chr>	<chr></chr>	<chr>></chr>	<dbl></dbl>
1	TORONTO	CITY	2018	01	tmax	d01	-7.9
2	TORONTO	CITY	2018	01	tmax	d02	-7.1
3	TORONTO	CITY	2018	01	tmax	d03	-5.3
4	TORONTO	CITY	2018	01	tmax	d04	-7.7
5	TORONTO	CITY	2018	01	tmax	d05	-14.7
6	TORONTO	CITY	2018	01	tmax	d06	-15.4
7	TORONTO	CITY	2018	01	tmax	d07	-1
0	торомто	OTTV	2010	0.1	+	400	2

Element

- Column element contains names of two different variables, that should each be in separate column.
- Distinct from eg. m1524 in tuberculosis data, that contained levels of two different factors, handled by separate.
- Untangling names of variables handled by pivot_wider.

Handling element

```
# A tibble: 355 \times 6
  station Year Month day tmax
                                    tmin
           <dbl> <chr> <chr> <dbl> <dbl> <dbl>
  <chr>
1 TORONTO CITY 2018 01
                         d01 -7.9 -18.6
2 TORONTO CITY 2018 01
                         d02 -7.1 -12.5
3 TORONTO CITY
                         d03 -5.3 -11.2
               2018 01
4 TORONTO CITY
               2018 01 d04 -7.7 -19.7
                              -14.7 - 20.6
5 TORONTO CITY
               2018 01
                         d05
6 TORONTO CITY
               2018 01
                         d06
                              -15.4 - 22.3
7 TORONTO CITY
               2018 01
                         d07
                               -1 -17.5
8 TORONTO CITY
               2018 01
                         d08
                                3 -1.7
```

Further improvements 1/2

- We have tidy data now, but can improve things further.
- mutate creates new columns from old (or assign back to change a variable).
- Would like numerical dates. separate works, or pull out number as below.
- select keeps columns (or drops, with minus). Station name has no value to us.

Further improvements 2/2

4

2018 01

```
weather %>%
 pivot_longer(d01:d31, names_to="day",
               values_to="temperature", values_drop_na = Ti
 pivot_wider(names_from=element, values_from=temperature)
 mutate(Day = parse_number(day)) %>%
  select(-station)
# A tibble: 355 x 6
   Year Month day tmax tmin
                                   Day
   <dbl> <chr> <dbl> <dbl> <dbl> <dbl> <
```

3 -1.7

7 2018 01 d07 -1 -17.5

d08

Final step(s)

- Make year-month-day into proper date.
- Keep only date, tmax, tmin:

Our tidy data frame

weather_tidy

```
# A tibble: 355 \times 3
  date
           tmax tmin
  <date> <dbl> <dbl>
 1 2018-01-01 -7.9 -18.6
 2 2018-01-02 -7.1 -12.5
 3 2018-01-03 -5.3 -11.2
4 2018-01-04 -7.7 -19.7
 5 2018-01-05 -14.7 -20.6
 6 2018-01-06 -15.4 -22.3
 7 2018-01-07 -1 -17.5
 8 2018-01-08 3 -1.7
 9 2018-01-09 1.6 -0.6
10 2018-01-10 5.9 -1.3
# i 345 more rows
```

Plotting the temperatures

▶ Plot temperature against date joined by lines, but with separate lines for max and min. ggplot requires something like

```
ggplot(..., aes(x = date, y = temperature)) + geom_point() +
  geom_line()
```

only we have two temperatures, one a max and one a min, that we want to keep separate.

- ➤ The trick: combine tmax and tmin together into one column, keeping track of what kind of temp they are. (This actually same format as untidy weather.) Are making weather_tidy untidy for purposes of drawing graph only.
- ▶ Then can do something like

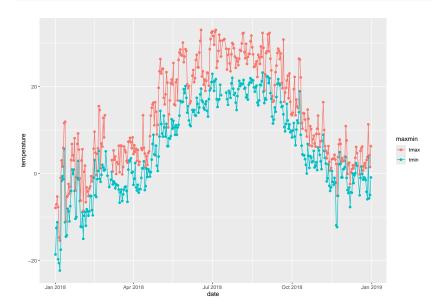

```
ggplot(d, aes(x = date, y = temperature, colour = maxmin))
+ geom_point() + geom_line()
```

to distinguish max and min on graph.

Setting up plot

- Since we only need data frame for plot, we can do the column-creation and plot in a pipeline.
- ► For a ggplot in a pipeline, the initial data frame is omitted, because it is whatever came out of the previous step.
- ➤ To make those "one column"s: pivot_longer. I save the graph to show overleaf:

g

Summary of tidying "verbs"

Verb	Purpose				
pivot_long@ambine columns that measure same thing into one pivot_wideTake column that measures one thing under different conditions and put into multiple columns					
separate	Turn a column that encodes several variables into several columns				
unite	Combine several (related) variables into one "combination" variable				

pivot_longer and pivot_wider are opposites; separate and unite are opposites.
