

Matched pairs Some data:

```
subject druga drugb
           2.0
           3.6
                  5.7
           2.6
                  2.9
           2.6
                  2.4
           7.3
                  3.3
          14.9
                 16.7
           6.6
           2.3
                  3.8
```

Matched pairs 1/2

- ▶ Data are comparison of 2 drugs for effectiveness at reducing pain.
 - ▶ 12 subjects (cases) were arthritis sufferers
 - Response is #hours of pain relief from each drug.
- In reading example, each child tried only one reading method.
- But here, each subject tried out both drugs, giving us two measurements.
- Possible because, if you wait long enough, one drug has no influence over effect of other.

Matched pairs 2/2

- ➤ Advantage: focused comparison of drugs. Compare one drug with another on same person, removes a lot of variability due to differences between people.
- Matched pairs, requires different analysis.
- ▶ Design: randomly choose 6 of 12 subjects to get drug A first, other 6 get drug B first.

Packages

```
library(tidyverse)
library(smmr) # for a sign test later
```

Reading the data

Values aligned in columns:

```
my_url <-
   "http://ritsokiguess.site/datafiles/analgesic.txt"
pain <- read_table(my_url)
pain %>% slice(1:6) # display first six rows
```

Paired t -test

```
Paired t-test
data: druga and drugb
t = -2.1677, df = 11, p-value = 0.05299
alternative hypothesis: true mean difference is not equal
95 percent confidence interval:
 -4.29941513 0.03274847
sample estimates:
mean difference
```

with(pain, t.test(druga, drugb, paired = TRUE))

► P-value is 0.053.

-2.133333

Not quite evidence of difference between drugs.

t-testing the differences

Likewise, you can calculate the differences yourself and then do a 1-sample t-test on them.

```
pain %>% mutate(diff = druga - drugb) -> pain
pain %>% slice(1:5)
```

t-test on the differences

▶ then throw them into t.test, testing that the mean is zero, with same result as before:

```
with(pain, t.test(diff, mu = 0))
```

One Sample t-test

```
data: diff
t = -2.1677, df = 11, p-value = 0.05299
alternative hypothesis: true mean is not equal to 0
95 percent confidence interval:
   -4.29941513   0.03274847
sample estimates:
mean of x
   -2.133333
```

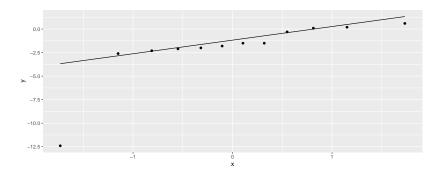

► Same P-value (0.053) and conclusion.

Assessing normality

- ▶ 1-sample and 2-sample t-tests assume (each) group normally distributed.
- Matched pairs analyses assume (theoretically) that differences normally distributed.
- ► How to assess normality? A normal quantile plot.

The normal quantile plot (of differences)

ggplot(pain,aes(sample=diff))+stat_qq()+stat_qq_line()

Points should follow the straight line. Bottom left one way off, so normality questionable here: outlier.

What to do instead?

- ▶ Matched pairs *t*-test based on one sample of differences
- the differences not normal (enough)
- so do *sign test* on differences, null median 0:

```
sign_test(pain, diff, 0)
```

```
$above_below
below above
9 3
```

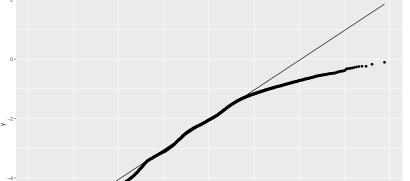

```
$p_values
```

```
alternative p_value
1 lower 0.07299805
2 upper 0.98071289
3 two-sided 0.14599609
```

Did we need to worry about that outlier?

Bootstrap sampling distribution of sample mean differences:

```
tibble(sim = 1:10000) %>%
  rowwise() %>%
  mutate(my_sample = list(sample(pain$diff, replace = TRUE)
  mutate(my_mean = mean(my_sample)) %>%
  ggplot(aes(sample = my_mean)) + stat_qq() + stat_qq_line
```

Comments

- no evidence of any difference between drugs (P-value 0.1460)
- lack in t-test, the low outlier difference pulled mean difference downward and made it look more negative than it should have been
- therefore, there really isn't any difference between the drugs.
