# Assumptions

Assumptions

▶ The t procedures we have seen so far come with assumption of normally-distributed data

▶ but how much does that normality matter?

▶ Central Limit Theorem says that sampling distribution of sample mean is "approximately normal" if sample size is "large".

▶ Hence same applies to difference of two sample means.

▶ How to use this in practice? Draw a picture and make a call about whether sample size large enough.

Blue Jays attendances

```
ggplot(jays, aes(sample = attendance)) +
  stat_qq() + stat_qq_line()
```
Comments

▶ Distribution of attendances somewhat skewed to the right (because of the short lower tail and the sort-of curve)
▶ Sample size $n = 25$ is reasonably large in Central Limit Theorem terms
▶ Use of t *may* be OK here despite skewed shape.

Learning to read

▶ Make normal quantile plots, one for each sample:

```
ggplot(kids, aes(sample = score)) +
  stat_qq() + stat_qq_line() +
  facet_wrap(~ group)
```

Comments

- with sample sizes over 20 in each group, these are easily normal enough to use a t-test.
- the (sampling distribution of the) difference between two sample means tends to have a more normal distribution than either sample mean individually, so that two-sample t tends to be better than you'd guess.

Pain relief

▶ With matched pairs, assumption is of normality of *differences*, so work those out first:

```
pain %>% mutate(diff = druga - drugb) -> pain
pain
```

```
# A tibble: 12 x 4
   subject druga drugb   diff
     <dbl> <dbl> <dbl>  <dbl>
 1       1   2     3.5   -1.5
 2       2   3.6   5.7   -2.1
 3       3   2.6   2.9   -0.300
 4       4   2.6   2.4    0.200
 5       5   7.3   9.9   -2.6
 6       6   3.4   3.3    0.100
 7       7  14.9  16.7   -1.80
 8       8   6.6   6      0.600
 9       9   2.3   3.8   -1.5
```

Normality of differences

```
ggplot(pain,aes(sample=diff)) + stat_qq() + stat_qq_line()
```

Comments

- This is very non-normal (the low outlier)
- The sample size of $n = 12$ is not large
- We should have concerns about our matched pairs t-test.

Doing things properly

▶ The right way to use a t procedure:
  ▶ draw a graph of our data (one of the standard graphs, or normal quantile plot)
  ▶ use the graph to assess sufficient normality given the sample size
  ▶ for a two-sample test, assess equality of spreads (boxplot easier for this)
  ▶ if necessary, express our doubts about the t procedure (for now), or do a better test (later).

Looking ahead

- ▶ Looking at a normal quantile plot and assessing it with the sample size seems rather arbitrary. Can we do better? (Yes: using the bootstrap, later.)
- ▶ What to do if the t procedure is not to be trusted? Use a different test (later):
  - ▶ one sample: sign test
  - ▶ two samples: Mood's median test
  - ▶ matched pairs: sign test on differences.
- ▶ If you have heard about the signed rank or rank sum tests: they come with extra assumptions that are usually not satisfied if normality fails.
